

Variables in Azure Data Factory

This post is part 21 of 25 in the series [Beginner's Guide to Azure Data Factory](#)

In the previous post, we talked about why you would want to build a dynamic solution, then looked at how to use [parameters](#). In this post, we will look at variables, how they are different from parameters, and how to use the set variable and append variable activities.

Variables

Parameters are external values passed *into* pipelines. They can't be changed *inside* a pipeline. **Variables**, on the other hand, are internal values that *live inside* a pipeline. They *can* be changed inside that pipeline.

Parameters and variables can be completely separate, or they can work together. For example, you can pass a parameter *into* a pipeline, and then use that parameter value in a **set variable** or **append variable** activity.

System Variables

In the previous post, I called out the syntax for dataset and pipeline [parameters](#). Did you notice the difference? :)

```
@dataset().ParameterName  
@pipeline().parameters.ParameterName
```

In a dataset, you can reference the parameter name directly. But in a pipeline, you have to first reference “parameters”. That’s because inside a pipeline, you have both parameters *and* **system variables**:

Add dynamic content

Clear contents

Filter...

Use [expressions.functions](#) or refer to [system.variables](#).

System variables

- Data factory name
Name of the data factory the pipeline run is running within
- Pipeline Name
Name of the pipeline
- Pipeline run ID
ID of the specific pipeline run
- Pipeline trigger ID
ID of the trigger that invokes the pipeline
- Pipeline trigger name
Name of the trigger that invokes the pipeline
- Pipeline trigger time
Time when the trigger that invoked the pipeline. The trigger time is the actual fired time, not the sch...
- Pipeline trigger type
Type of the trigger that invoked the pipeline (Manual, Scheduler)

Functions

Parameters

To use **system variables**, you reference them in a similar way to parameters:

```
@pipeline().DataFactory
@pipeline().Pipeline
@pipeline().RunId
@pipeline().TriggerId
@pipeline().TriggerName
@pipeline().TriggerTime
@pipeline().TriggerType
```

User Variables

User variables are slightly different, though. You reference them by their name:

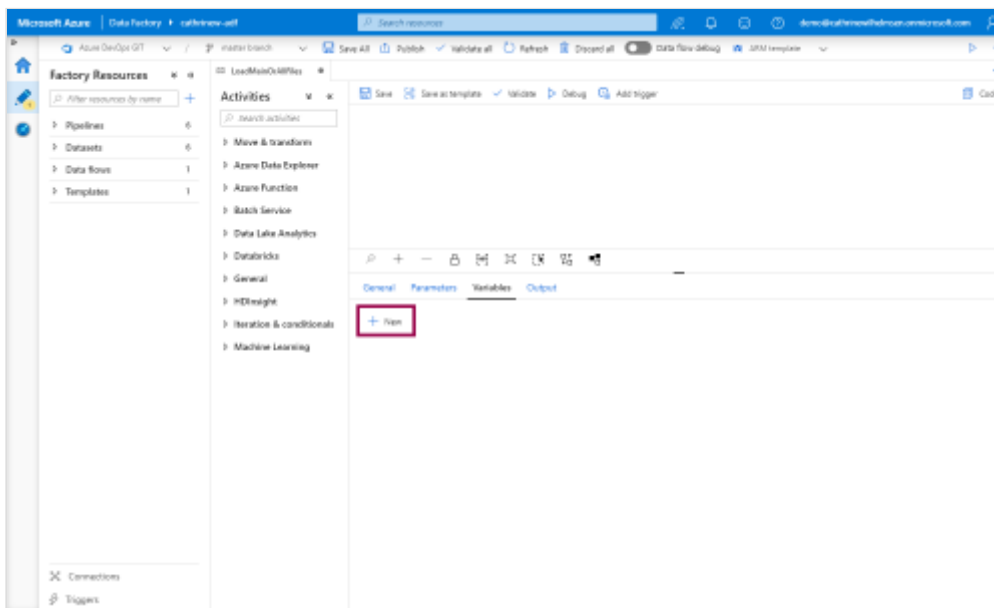

```
@variables('VariableName')
```

Let's see how this works!

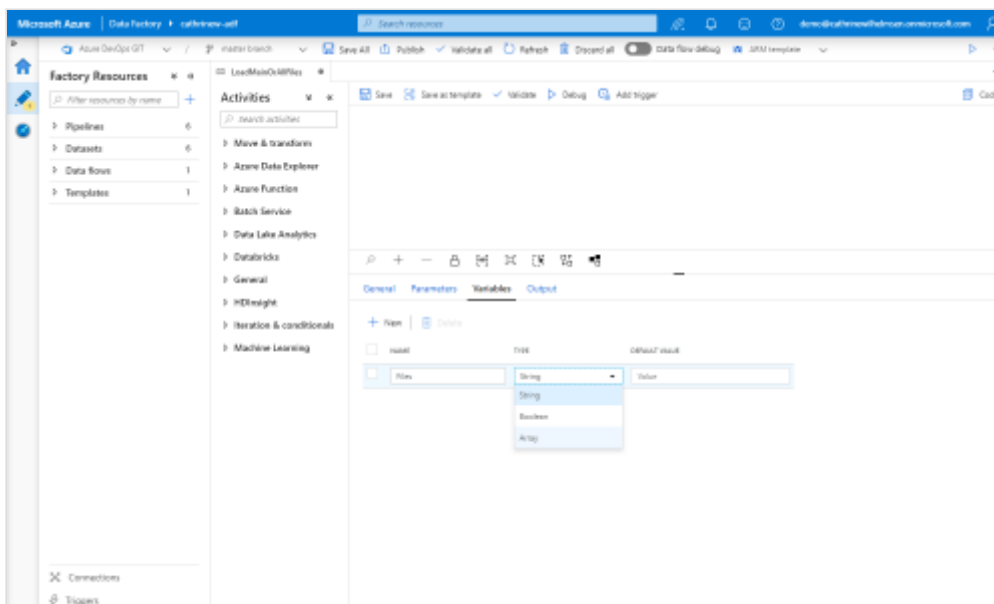

In this example, we will build a new pipeline to show how a variable can be used and updated. Our goal is to create a pipeline that can be used to load *some* or *all* the files from [Rebrickable](#).

Create Variables

Create a new pipeline, go to the variables properties, and click **+ new**:

Give the variable a **name** and choose the **type**. You can specify a **default value** if you want:

Create two variables. One *array* variable named **Files**, and one *string* variable named **ListOfFiles**:

NAME	TYPE	DEFAULT VALUE
Files	Array	Value
ListOfFiles	String	Value

Then, create a *bool* parameter named **LoadAllFiles**:

NAME	TYPE	DEFAULT VALUE
LoadAllFiles	Bool	false

Set Variable

Add a new **set variable** activity, go to **variables**, and choose the **Files** variable:

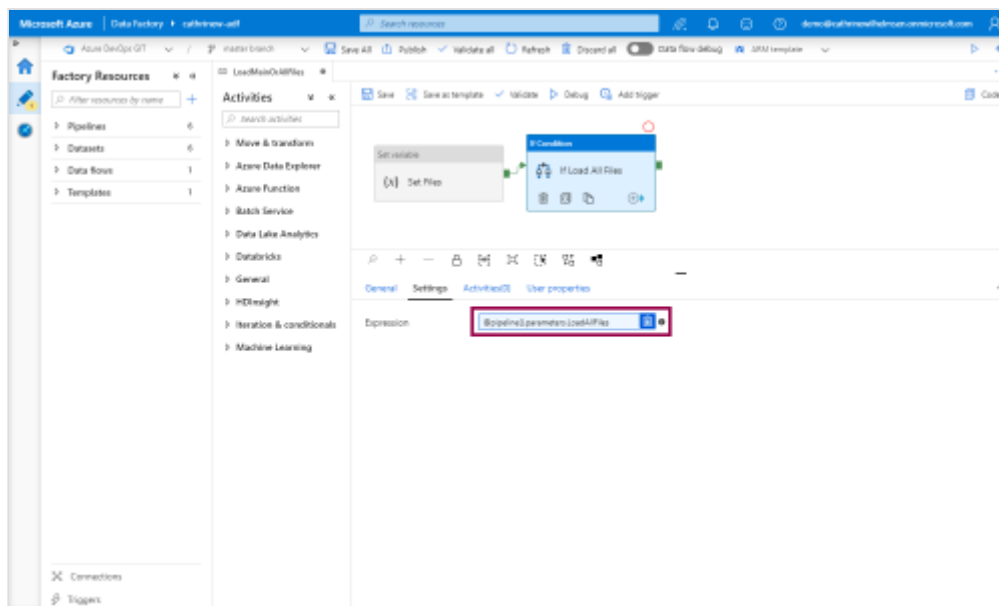

The screenshot shows the 'Set variable' activity configuration in Azure Data Factory. The 'Variables' tab is active, and the 'Files' variable is selected from the 'Name' dropdown menu.

Add the array **value** *"colors,inventories,inventory_parts,part_categories,parts,sets,themes"* (without quotes and spaces):

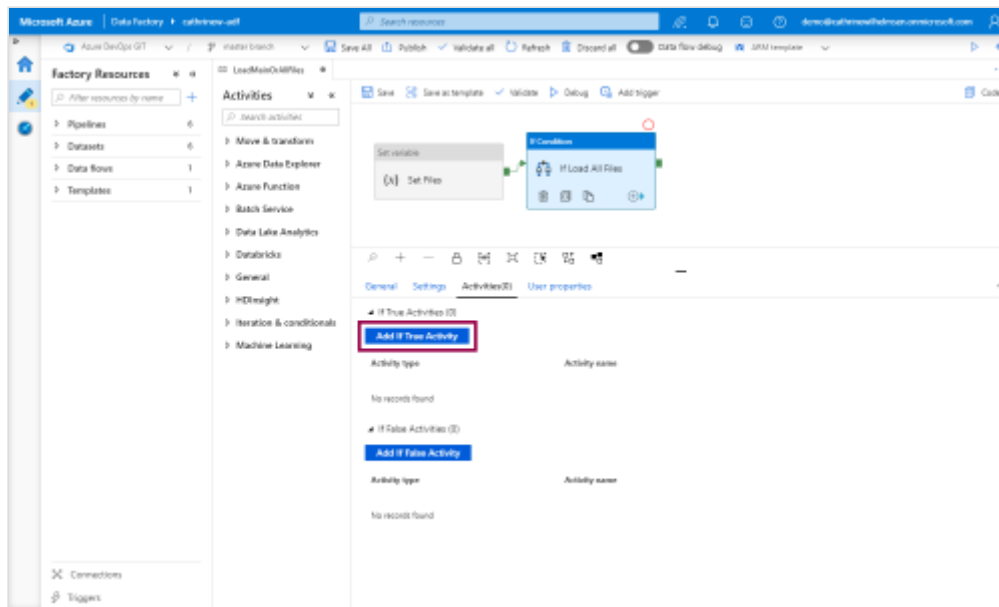

These are the seven **Rebrickable** files I consider the main files.

Then, add an **if condition**, and use **LoadAllFiles** parameter as the expression. This is a *bool* parameter that will evaluate to *true* or *false*:

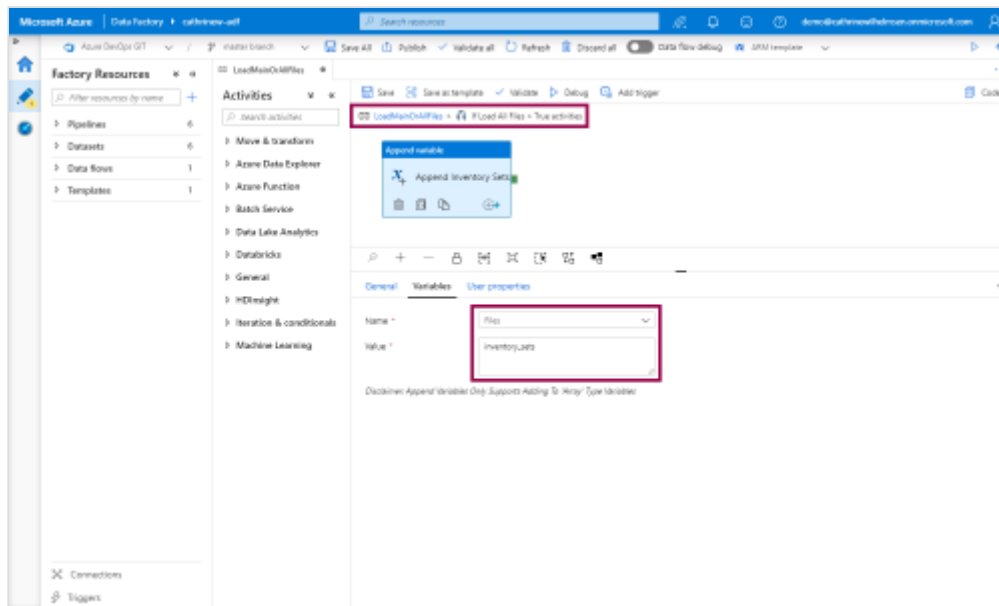

(Hee hee, I'm sneaking in new activities in this series 😊)

Add an **if true activity**:

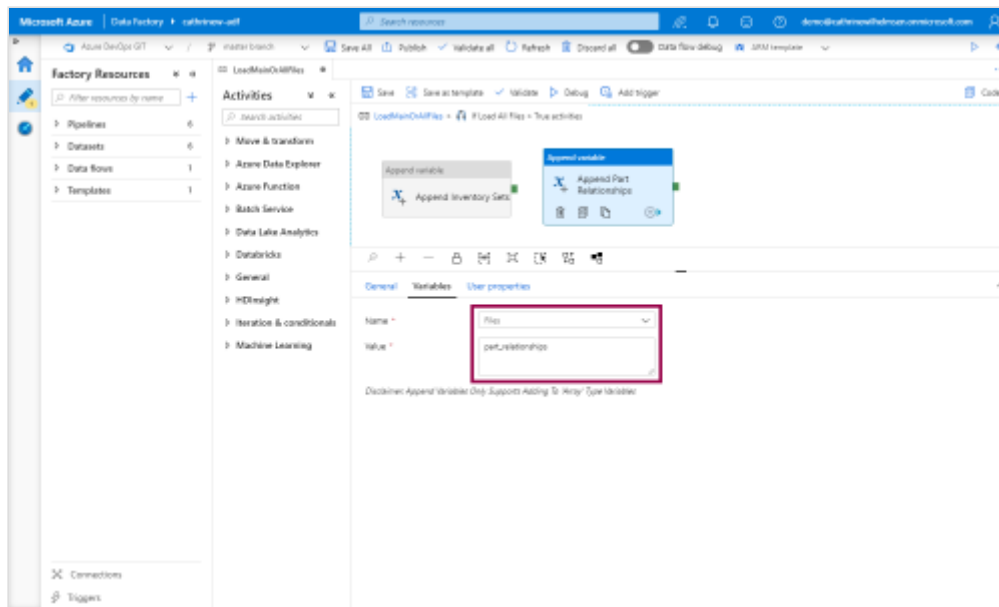

Append Variable

Inside the **true activities**, add an **append variable** activity. Choose the **Files** variable, and use the value `"inventory_sets"`:

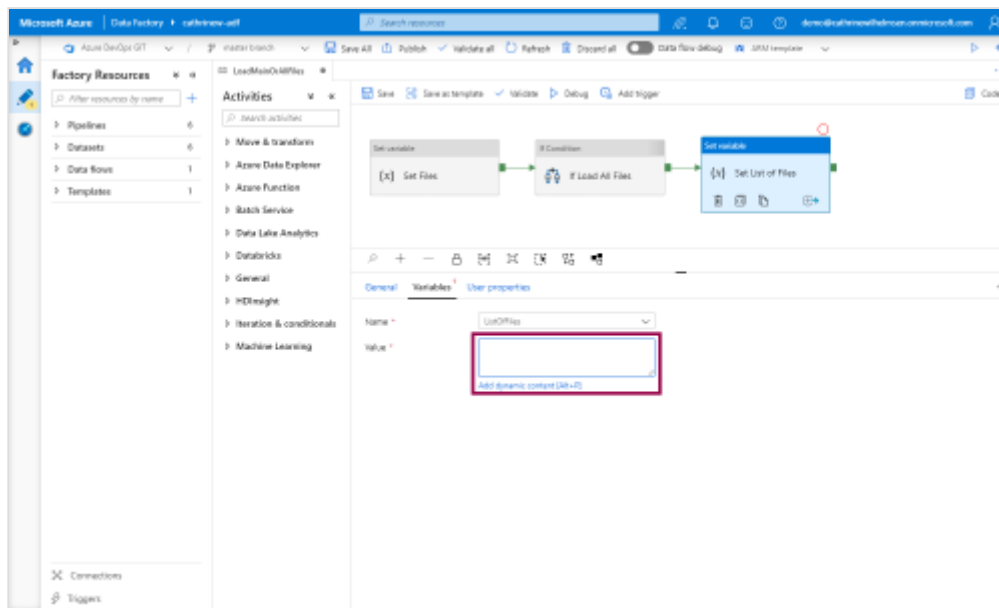

Add a second **append variable** activity for `"part_relationships"`:

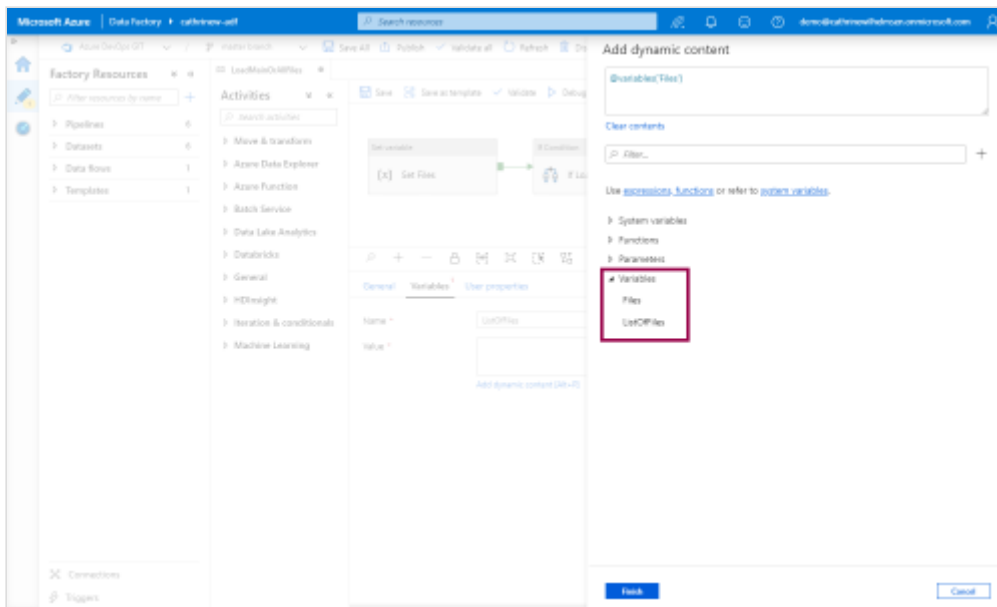

Use Variables

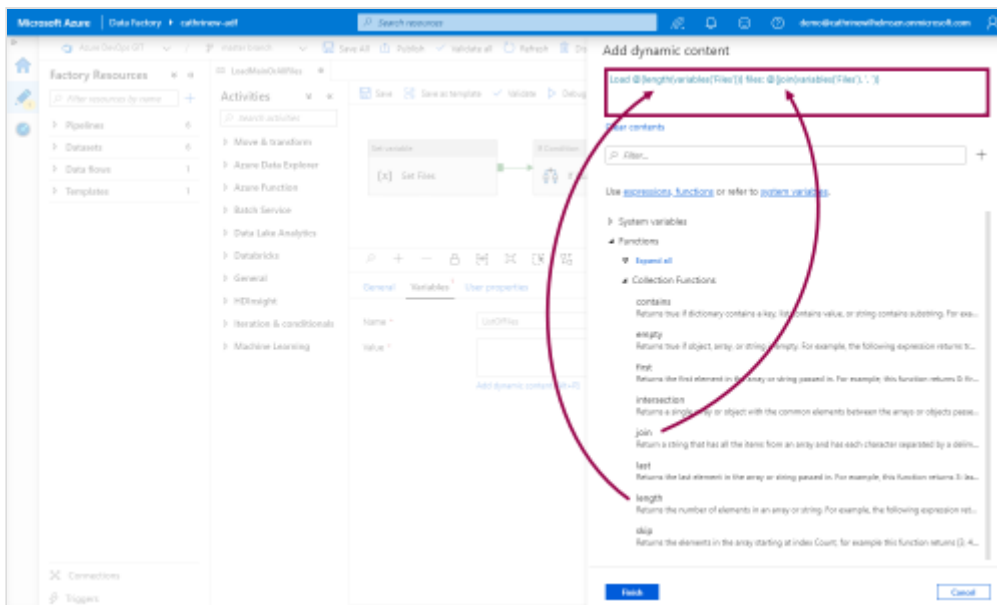

Finally, add another **set variable** activity, and click to **add dynamic content**:

In the **add dynamic content** pane, you can click to add a **variable**:

You can use a combination of **variables**, **functions**, and **string interpolation**:

Let's test our pipeline! Click **debug**:

And set **LoadAllFiles** to **false**:

Click on the **set files output**. We will see our array with **seven files** listed:

Click on the **set list of Files output**. We will see the **result of the expression** using the variable, functions, and string interpolation. It says *"Load 7 files: colors, inventories, inventory_parts, part_categories, parts, sets, themes"*:

Let's try again! **debug** the pipeline again, but this time, set **LoadAllFiles** to **true**:

This, time, we see that the **append variable activities** also ran :) We also get a different **output**:

Summary

In this post, we looked at variables and how they are different from parameters. Then we built a pipeline to show how to use the set variable and append variable activities.

We took a sneak peek at working with *arrays* in this post, but we didn't actually *do* anything with it. We just showed the output.

In the next post, however, we will take a closer look at arrays. We will see how they can control a **foreach loop**!
